

ABSTRACT OF THE DISCLOSURE

It is an object of the present invention to provide an encoding device and an encoding method that allow even faster speeds to be achieved by
5 reducing the waiting time during which variable-length encoding is performed. An encoding device performing run-length encoding and variable-length encoding sequentially inputs one block of $m \times n$ data, determines whether a value of each unit of input data is 0 (zero), stores the results of the determination to an information register and stores input data
10 to a data buffer, controls the reading of data from the data buffer based on the results of the determination, performs run-length encoding using the data read from the data buffer and the results of the determination, and performs variable-length encoding using as a data pair the data and the number of consecutive data having a value of 0 (zero).
